

Part 6

Memory & Addressing

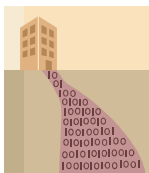

What is Memory?

Its... um.... I forgot....

Computer Memory

- Assembly offers you vast control over memory
- Understanding it...
 - is vital to becoming a great assembly programmer
 - and understanding computer architecture

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

3

What is Memory?

- Memory is essentially a long list of bytes
- Memory is sometimes referred to as *storage*
- This is because it stores both running programs and their related data

Memory	
0	01000100
1	01000011
2	01101111
3	01101111
4	01101011

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

4

Memory Addresses

- Memory is divided into a storage locations that can hold 1 byte (8 bits) of data
- Each byte has an *address*
 - unique value that refers to that specific byte
 - used to locate the exact byte the processor wants

Memory	
0	01000100
1	01000011
2	01101111
3	01101111
4	01101011

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

5

Metaphor for Memory

- Think of memory as a *set of mailboxes*
- Each mailbox can contain a piece of data (byte)
- Each mailbox has a unique number

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

6

Metaphor for Memory

- ... or think of memory as a *group of boxes*
- Each box belongs to the same variable
- Each box has a unique number

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

7

Endianness

The "proper" order of things

So Many Bytes...

- On a 64-bit system, each word consists of 8 bytes
- So, when any 64-bit value is stored in memory, each of those 8 bytes must be stored
- However, question remains: *What order do we store them?*

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

9

So Many Bytes...

- Do we store the least-significant byte (LSB) first, or the most-significant (MSB)?
- As long as a system always follows the same format, then there are no problems
- ... but different systems use different approaches

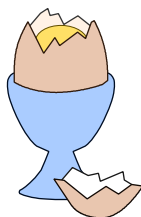

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

10

Big Endian vs. Little Endian

- Big-Endian approach
 - store the MSB first
 - used by Motorola & PowerPC
- Little-Endian approach
 - store the LSB first
 - used by Intel
 - appears "backwards" in editors

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

11

Example Unsigned Integer (4 Byte)

1,188,852,977

46	DC	74	F1
----	----	----	----

Most significant
Byte

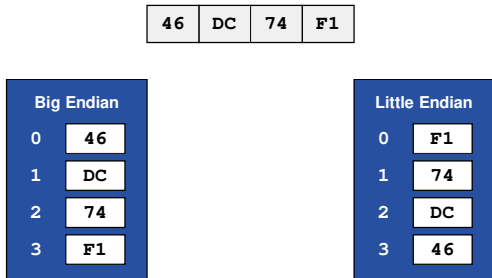

Least significant
Byte

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

12

Big Endian vs. Little Endian

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

13

No "End" to Problems

- *There is a problem...*
if two systems use different formats, data will be interpreted incorrectly!
- For example:
 - a **little**-endian system reads a value stored in **big**-endian
 - a **big**-endian system reads a value stored in **little**-endian

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

14

No "End" to Problems

- So, whenever data is read from secondary storage, you **cannot** assume it will be in your processor's format
- This is compounded by file formats (gif, jpeg, mp3, etc...) which are also inconsistent

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

15

Example File Format Endianness

File Format	Endianness
Adobe Photoshop	Big Endian
Windows Bitmap (.bmp)	Little Endian
GIF	Little Endian
JPEG	Big Endian
MP4	Big Endian
ZIP file	Little Endian

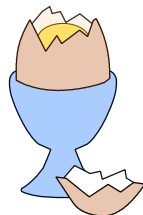

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

16

So... who is correct?

- So, what is the correct and superior format?
- Is it Intel (little endian)?
- ...or the PowerPC (big endian) correct?

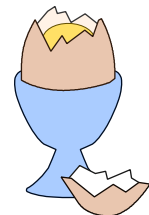

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

17

So... who is correct?

- In reality neither side is superior
- Both formats are equally correct
- Both have minor advantages in assembly... but nothing huge

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

18

Gulliver's Travels

4/10/2018

Sacramento State - Cook - CSIS 35 - Spring 2018

19

Addressing Modes

How to interact with memory

Addressing Modes

- Processor instructions often need to access memory to read values and store results
- So far, we have used registers to read and store single values
- However, we need to:
 - access items in an array
 - follow pointers
 - and more!

4/10/2018

Sacramento State - Cook - CSIS 35 - Spring 2018

21

Addressing Modes

- How a processor can locate and read data from memory is called an *addressing mode*
- Information combined from registers, immediates, etc... to create a target address
- Modes vary greatly between processors

4/10/2018

Sacramento State - Cook - CSIS 35 - Spring 2018

22

4 Basic Addressing Modes

1. Immediate (part of instruction after the opcode bits)
2. Value stored in a register
3. Memory address specified in the instruction
4. Memory address pointed to by a register

4/10/2018

Sacramento State - Cook - CSIS 35 - Spring 2018

23

Immediate Addressing

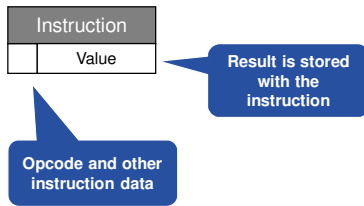

- Immediate addressing is one of the most basic modes found on a processor
- Often a value is stored as part of the instruction
- As the result, it is *immediately* available
- Very common for assigning constants

4/10/2018

Sacramento State - Cook - CSIS 35 - Spring 2018

24

Immediate Addressing

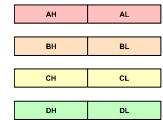

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

25

Register Addressing

- Register addressing is used in practically all computer instructions
- A value is read from or stored into one of the processor's registers
- Instruction contains the register's **number**

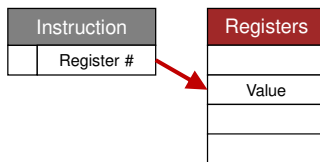

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

26

Register Addressing

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

27

Direct Addressing

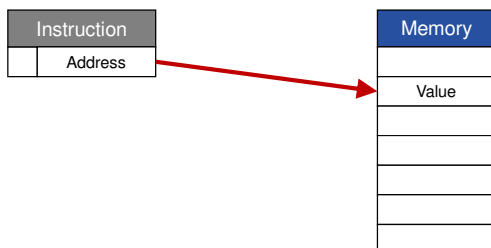

- In *direct* addressing, the processor reads data directly from the computed address
- Commonly used to:
 - get a value from a "variable"
 - read items in an array
 - etc...

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

28

Direct Addressing

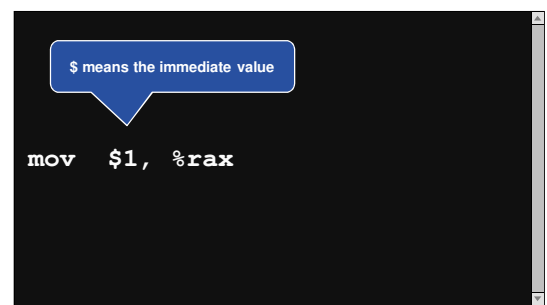

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

29

Example: Immediate

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

30

Example: Direct

```
.data
Total:
    .quad 0

.text
.global _start
_start:
    mov Total, %rax
```

64 bit integer. With an initial value of 0.

No \$. Get the 8 bytes at this address. Doesn't store "the" address in rax.

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

31

Register Indirect Addressing

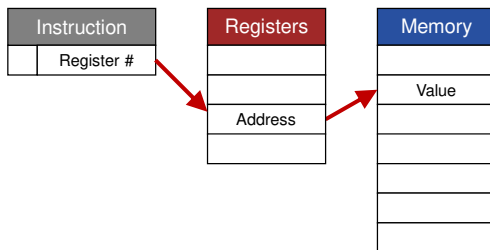

- *Register Indirect* uses a register is used to store the address
- Same concept as a *pointer*
- Because the address is in a register...
 - processor does have to go to memory get it
 - it is just as fast as direct addressing
 - ... and very common

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

32

Register Indirect Addressing

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

33

Relative Addressing

- In *relative addressing*, a value is added to a system register (e.g. program counter)
- Advantages:
 - instruction can just store the *difference* (in bytes) from the current instruction address
 - takes less storage than a full 64-bit address
 - it allows a program to be stored anywhere in memory – *and it will still work!*

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

34

Relative Addressing

- Often used in conditional jump statements
 - only need the to store the number of bytes to jump – either up or down
 - so, the instruction only stores the value to add to the program counter
 - practically all processors us this approach
- Also used to access local data – load/store

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

35

Behind the
Scenes of
Arrays

All the mystery is revealed!

Arrays

- Computers do not have an 'array' data type
- So, how do you have array variables?
- When you create an array...
 - you allocate a block of memory
 - each element (cell) is located sequentially in memory – one right after each other

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

37

Arrays

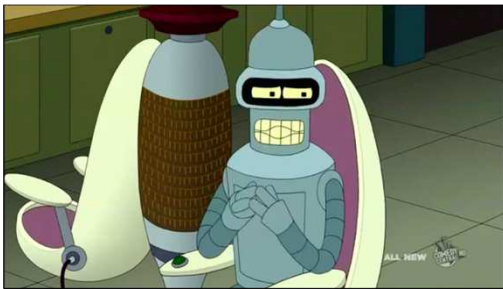

- Every byte in memory has an address
- This is just like an array
- To get an array cell
 - we merely need to compute the address
 - we must also remember that some values take multiple bytes – *so there is math*

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

38

Arrays

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

39

Array Math Example

- Start of our block of memory (buffer) is at address **2000**
- The first array cell is at 2000
- Arrays consists of bytes...
 - the second is at **2001**
 - the third is at **2002**
 - the fourth at **2003**
 - etc...

2000	H
2001	e
2002	l
2003	l
2004	o

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

40

Array Math Example – 16 bit

- First cell uses 2000... 2001
- Since each cell is 2 bytes...
 - the second is at **2002**
 - the third is at **2004**
 - the fourth at **2006**
 - etc...

2000	F0A3
2002	042B
2004	C1F1
2006	0D0B
2008	9C2A

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

41

Array Math Example – 64 bit

- The case with 64-bit integers is exactly the same
- A 64-bit integer takes **8** bytes in memory
- So, as a result, **each cell will require 8 bytes of memory**

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

42

Array Math Example – 64 bit

- First cell uses 2000... 2007
- Second is at 2008
- Third is at 2016
- Fourth at 2024
- etc...

2000	446576696E20436F
2008	6F6B000000000000
2016	53616372616D656E
2024	746F205374617465
2032	4353433335000000

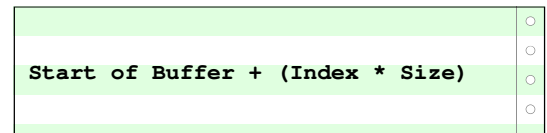

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

43

Behind the Scenes...

- So, when an array element is read, internally, a mathematical equation is used
- It takes into account the start of the first cell, the array index, and the size of each element

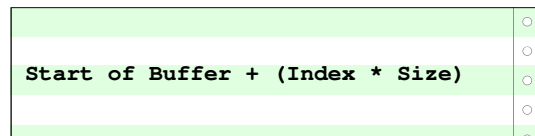

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

44

Behind the Scenes...

- This is why the C Programming Languages uses zero as the first array element*
- If zero is used with this formula, it gets the start of the buffer

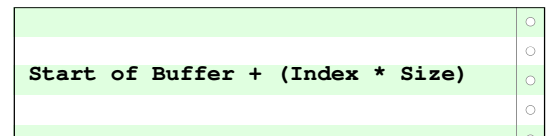

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

45

Behind the Scenes...

- Java uses zero-indexing because C does
- ... and C does so it can create efficient assembly!

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

46

Addressing on the x64

Grabbing any byte

Addressing on the x64

- The Intel x64 supports direct, indirect, indexing and scaling
- So, the Intel is very versatile in how it can access memory
- This is typical of CISC-ish architectures

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

48

Effective Addresses

- Using the addresses stored in memory, registers, etc... is useful in programs
- Often programs contain *groups* of data
 - fields in an abstract data type
 - cells in an array
 - entries in a large table etc...

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

49

Effective Addresses

- Processors have the ability to create an *effective address* by combining data
- How it works:
 - starts with a base address
 - then adds a value (or values)
 - finally, uses this temporary value as the actual address

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

50

Terminology

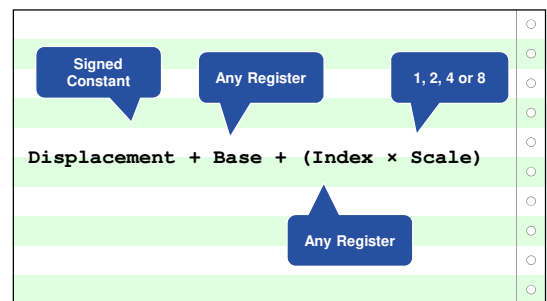

- Base-address* is the initial address
- Displacement (aka offset)* is a constant (immediate) that is added to the address
- Index* is a *register* added to the address
- Scale* used to multiply the index before adding it to the address

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

51

x64 Effective Address Formula

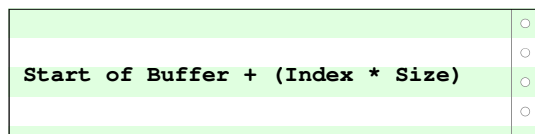

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

52

Behind the Scenes...

- But wait, doesn't that formula look familiar?
- The addressing term "scale" is basically equivalent to "size" in this example
- Addressing helps us use arrays!

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

53

Addressing Notation in Assembly

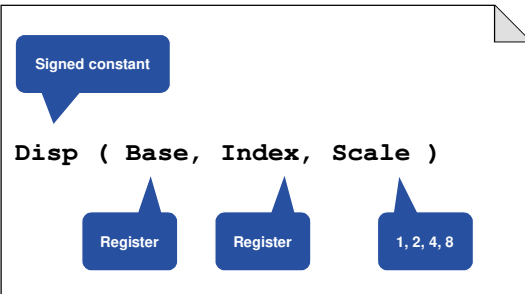

- The AT&T / GAS notation allows you to specify the full addressing
- The notation is a tad terse, and the alternative, Intel notation, is easier to read
- However...
 - you will get used to it quite quickly
 - look at what you can read already!

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

54

AT&T / GAS Operand Notation

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

55

AT&T / GAS Notation

Mode	Syntax	Java Equivalent
Immediate	\$value	value
Register	%name	Registers[name]
Direct	address	Memory[address]
Direct Indexed	address(%reg)	Memory[address + %reg]
Indirect	(%reg)	Memory[%reg]
Indirect Indexed	(%reg, %reg)	Memory[%reg + %reg]
Indirect Indexed Scaled	(%reg, %reg, scale)	Memory[%reg + %reg × scale]

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

56

Addressing Notation in Assembly

- When you write an assembly instruction...
 - you specify all 4 addressing features
 - however, notation fills in the "missing" items
- For example: for direct addressing...
 - Displacement → Address of the data
 - Base → Not used
 - Index → Not used
 - Scale → 1, which is irrelevant without an Index

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

57

How Many Bytes

- When you store data into a register, the assembler knows (*by looking at the size of the register*) how much is going to be accessed
- However, when using addressing,
 - it sometimes is not obvious if you are accessing a byte, 2 bytes, etc...
 - this will cause a very cryptic error

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

58

How Many Bytes

- To address this issue, AT&T/GAS notation places a single character after the instruction name
- This suffix will tell the assembler how many bytes will be accessed during the operation

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

59

How Many Bytes

Suffix	Meaning
b	byte
s	short (2 bytes)
l	long (4 bytes)
q	quad (8 bytes)

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

60

Example: Direct Index

Using the EDI register for indexing, but you can use any GP register

```
mov $1, %rdi
movb $33, Text(%rdi)
```

ASCII 33 → !

Text		
H	0	
!	1	
L	2	
L	3	
O	4	

4/10/2018 Sacramento State - Cook - CSc 35 - Spring 2018 61

Example: Direct Index (Scale of 2)

```
mov $1, %rdi
movb $33, Text(,%rdi,2)
```

Each "cell" is 2 bytes

Text		
H	0	
E	1	
!	2	
L	3	
O	4	

4/10/2018 Sacramento State - Cook - CSc 35 - Spring 2018 62

Example: Direct Index (Scale of 4)

```
mov $1, %rdi
movb $33, Text(,%rdi,4)
```

Each "cell" is 4 bytes

Text		
H	0	
E	1	
L	2	
L	3	
!	4	

4/10/2018 Sacramento State - Cook - CSc 35 - Spring 2018 63

Example: Register Indirect

The value of Text – an address

```
mov $Text, %rax
movb $33, (%rax)
```

Indirect. Base is rax

Text		
!	0	
E	1	
L	2	
L	3	
O	4	

4/10/2018 Sacramento State - Cook - CSc 35 - Spring 2018 64

Example: Register Indirect Index

```
mov $Text, %rax
mov $1, %rdi
movb $33, (%rax,%rdi)
```

Base Index

Text		
!	0	
L	1	
L	2	
L	3	
O	4	

4/10/2018 Sacramento State - Cook - CSc 35 - Spring 2018 65

Example: Reg Indirect Index (Scale 2)

```
mov $Text, %rax
mov $1, %rdi
movb $33, (%rax,%rdi,2)
```

Scale

Text		
H	0	
E	1	
!	2	
L	3	
O	4	

4/10/2018 Sacramento State - Cook - CSc 35 - Spring 2018 66

Example: Reg Indirect Index (Scale 4)

```
mov $Text, %rax
mov $1, %rdi
movb $33, (%rax,%rdi,4)
```

Text	H	0
	E	1
	L	2
	L	3
	!	4

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

67

For Loop: 0 to 4

```
mov $0, %rdi
mov $33, %ch

Loop:
    cmp $4, %rdi
    jg End

    movb %ch, Text(%rdi)
    add $1, %rdi
    jmp Loop

End:
```

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

68

For Loop: 0 to 4 - Before

```
mov $0, %rdi
mov $33, %ch

Loop:
    cmp $4, %rdi
    jg End

    movb %ch, Text(%rdi)
    add $1, %rdi
    jmp Loop

End:
```

Text	H	0
	E	1
	L	2
	L	3
	O	4

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

69

For Loop: 0 to 4 - After

```
mov $0, %rdi
mov $33, %ch

Loop:
    cmp $4, %rdi
    jg End

    movb %ch, Text(%rdi)
    add $1, %rdi
    jmp Loop

End:
```

Text	!	0
	!	1
	!	2
	!	3
	!	4

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

70

Buffers

Creating your own space

Buffers

- A *buffer* is any allocated block of memory that you plan to use
- This can hold anything:
 - text
 - image
 - file
 - etc....

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

72

Buffers

- There are several **directives** which will allocate space
- We have covered a few of them, but there are many – all with a specific purpose

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

73

A few directives that create space

Directive	What it does
<code>.ascii</code>	Allocate enough space to store an ASCII string
<code>.quad</code>	Allocate 8 byte blocks with an initial value(s)
<code>.byte</code>	Allocate byte(s) with an initial value(s)
<code>.space</code>	Allocate any size of empty bytes (with initial values).

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

74

ASCII Directive Creates a Buffer

Text:

```
.ascii "Hello\0"
```

Creates 6 bytes to store Hello. They are stored consequently

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

75

Same Thing!

Text:

```
.byte 'H'  
.byte 'e'  
.byte 'l'  
.byte 'l'  
.byte 'o'  
.byte '\0'
```

Created byte by byte

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

76

This works too!

Text:

```
.ascii "Hello"  
.byte 0
```

Directives just create space. So, this creates a byte after the ASCII text.

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

77

Create a Buffer of Any Size

Text:

```
.space 30
```

Create 30 bytes (defaults to 0x20 which is a space)

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

78

Create a Buffer of Any Size

Text :

```
.space 30, 0
```

Create 30 bytes.
All of which are 0.

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

79

Buffer Overflow

With Great Power
Comes Great Responsibility

Buffer Overflow

- Operating systems protect programs from having their memory / code damaged by another program
- However...operating systems don't protect programs from damaging *themselves*

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

81

Buffers & Programs

- In memory, a running program's data is often stored next to its instructions
- This means...
 - if the end of a buffer is exceeded, the program can be read/written
 - this is a common hacker technique to modify a program *while it is running!*

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

82

Example Program

```
.data
Kitty:
.ascii "Cat"

Puppy:
.ascii "Dog"

.text
.global _start
_start:
```

Kitty	43	C
	61	a
	74	t
Puppy	44	D
	6F	o
	67	g
_start	?	
...		

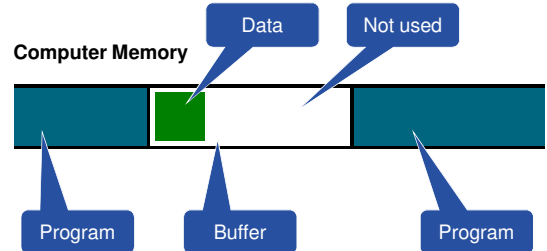

Start of program

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

83

Buffer Overflow – How it Works

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

84

Buffer Overflow

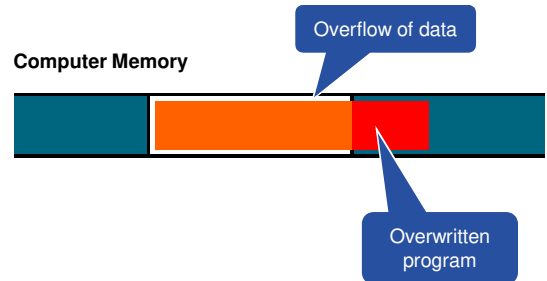

- It is possible to store too much information – resulting in a *buffer overflow*
- The extra bytes will overwrite part of the running program – changing it!

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

85

Buffer Overflow – How it Works

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

86

Bad Indexing

- It is possible to accidentally change data stored in the *different* buffers
- In assembly, you have full control over your allocated memory
- With great power comes great responsibility*

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

87

Wrong Buffer Changed

```
.data
Kitty:
    .ascii "Cat\0"
Puppy:
    .ascii "Dog\0"

.text
.global _start
_start:
    mov $4, %rdi
    movb $72, Kitty(%rdi)
```

4 bytes. Character indexes from 0 to 3

72 is ASCII 'H'

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

88

Wrong Buffer Changed

```
.data
Kitty:
    .ascii "Cat\0"
Puppy:
    .ascii "Dog\0"

.text
.global _start
_start:
    mov $4, %rdi
    movb $72, Kitty(%rdi)
```

Buffer	Index	Value	Character
Kitty	43	C	C
	61	a	a
	74	t	t
	00		\0
Puppy	44	D	D
	6F	o	o
	67	g	g
	00		\0

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

89

Wrong Buffer Changed

```
.data
Kitty:
    .ascii "Cat\0"
Puppy:
    .ascii "Dog\0"

.text
.global _start
_start:
    mov $4, %rdi
    movb $72, Kitty(%rdi)
```

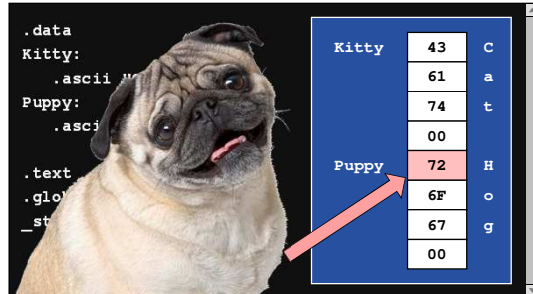

Buffer	Index	Value	Character
Kitty	43	C	C
	61	a	a

x64 Register Mastery

Choosing the right register (and mode)

x64 Register Mastery

- x64 has 8-bit, 16-bit, 32-bit, and 64-bit registers
- They are different parts of the same register (e.g. ah, al, ax, rax are the "A" register)
- Using the correct one is vital to making your program work

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

93

x64 Register Mastery

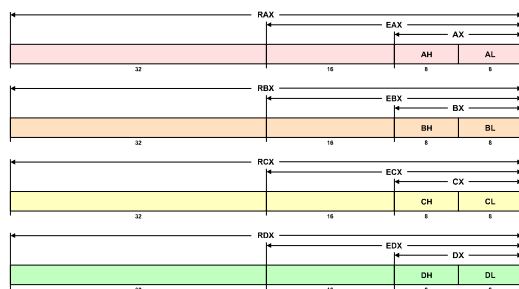

- When you load/store data, the register will grab as many bytes as it can store
- So...
 - 8-bit register will access 1 byte
 - 16-bit register will access 2 bytes
 - 32-bit register will access 4 bytes
 - 64-bit register will access 8 bytes
- Using the wrong size can cause problems

96

New 64-bit Registers

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

97

Example Program

```
.data
Message:
    .ascii "Hello!!\0"

.text
.global _start

_start:
    mov Message, %rax
```

Creates 8 bytes using ASCII values

rax is 64-bit (8 bytes)

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

98

Example Program

```
.data
Message:
    .ascii "Hello!!\0"

.text
.global _start

_start:
    mov Message, %rax
```

Message	48	H
	65	e
	6C	l
	6C	l
	6F	o
	21	!
	21	!
	00	\0

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

99

Example Program

```
.data
Message:
    .ascii "Hello!!\0"

.text
.global _start

_start:
    mov Message, %rax
```

Message	48	H
	65	e
	6C	l
	6C	l
	6F	o
	21	!
	21	!
	00	\0

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

100

Example Program

- In that example, we used a 64-bit register (rax) to read from the address "Message".
- It grabbed 8 bytes!
- If we wanted to compare a single character to another using 64-bit registers...
 - it would fail – we grabbed too much!
 - it would also compare those extra characters

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

101

Example Program

```
.data
Message:
    .ascii "Hello!!\0"

.text
.global _start

_start:
    mov Message, %al
```

Message	48	H
	65	e
	6C	l
	6C	l
	6F	o
	21	!
	21	!
	00	\0

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

102

This works, but gives a warning...

```

.data
Message:
    .ascii "Hello!!\0"

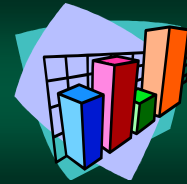

.text
.global _start
_start:
    movb Message, %rax
    
```

Address	Value	Character
48	48	H
49	65	e
50	6C	l
51	6C	l
52	21	!
53	21	!
54	00	\0

Tables

How to Organize Data

Data Tables

- In assembly, you have full control of memory
- You can take advantage of these to create tables
- They can contain any data – from integers, to characters, to addresses

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

105

Accessing Each Cell

Use register to hold table index

```

mov    $1, %rdi
movb   Text(%rdi), %ah
    
```

Index	Character
0	H
1	E
2	L
3	L
4	O

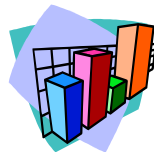

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

106

Tables of Integers

- Tables can contain *anything!*
- Often, they are used to store integers & addresses (8 bytes on a 64-bit system)
- Just make sure to use the scale feature!

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

107

Table of Long Integers

Years:

```

.quad 1776
.quad 1783
.quad 1846
.quad 1850
.quad 1947
    
```

8 Bytes each

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

108

Table of Long Integers

Years:

```
.quad 1776
.quad 1783
.quad 1846
.quad 1850
.quad 1947
```

Years	1776	0
	1783	8
	1846	16
	1850	24
	1947	32

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

109

Accessing Each Cell

Table index 1

```
mov $1, %rdi
movq Years(,%rdi,8), %rax
```

Note the scale!

Years	1776	0
	1783	8
	1846	16
	1850	24
	1947	32

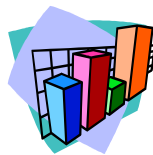

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

110

Jump Table

- You can also jump to a value stored in a register
- ... which means you can create a jump table!

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

111

Table of Addresses

JumpTable:

```
.quad ScanInt
.quad PrintInt
```

4/10/2018

Sacramento State - Cook - CSc 35 - Spring 2018

112

Calling a Register (a tad odd)

```
mov $1, %rdi
mov JumpTable(,%rdi,8), %rbx

call *%rbx
```

AT&T notation
requires an
asterisk
