

Binary Search

Cutting the problem in half... many times

- A *binary search* is an fast and efficient way to search an array
- Algorithm works like the classic "secret number game"
- Requires that the array is sorted before the search

6/26/2019

Sacramento State - Summer 2019 - C-Sci 130 - Cook

- Starts knowing the max & min values
 - in the case of arrays, this is the min and max index
 - in the number game, it is the min and max value
- Algorithm continues
 - it looks at the midpoint between the first and last
 - if the value > target, the max is set to the midpoint
 - if the value < target, the min is set to the midpoint
 - *this eliminates half of the numbers each iteration*

A diagram showing a sorted array of 12 elements: [3, 5, 8, 12, 23, 30, 35, 42, 47, 52, 65, 77, 81]. Above the array, three arrows indicate pointer positions: a red arrow labeled 'Min' points to the first element (3), an orange arrow labeled 'Max' points to the 6th element (30), and a red arrow labeled 'Mid' points to the 7th element (35).

8

Benefits

- The binary search is incredibly efficient and absolutely necessary for large arrays
- Any item can be found only $\log_2(n)$ searches!
- However, since array must be sorted, sorting algorithms are equally vital

6/26/2019

Sacramento State - Summer 2019 - CSc 130 - Cook

9

Maximum # of Searches

Array Size	Sequential Search	Binary Search
10	10	4
100	100	7
1,000	1,000	10
10,000	10,000	14
100,000	100,000	17
1,000,000	1,000,000	20
10,000,000	10,000,000	24
100,000,000	100,000,000	27
1,000,000,000	1,000,000,000	30

Dictionaries

.. and "ADT" is not in a human one!

Moving Past Arrays....

- A *collection* is general term for an group of data items
- So, this can include arrays, linked lists, stacks, queues, and much more
- So far, we have just used arrays – which are indexed by an integer

6/26/2019

Sacramento State - Summer 2019 - CSc 130 - Cook

12

Moving Past Arrays....

- Are there are other ways to index data?
- Yes.
 - any object can be used as an index
 - e.g. strings, integers, pictures, etc...

6/26/2019

Sacramento State - Summer 2019 - CSc 130 - Cook

13

Dictionaries

- Collections of objects indexed by other objects are called *dictionaries*
- They have a few alternative names...
 - keyed tables*
 - symbol tables*
 - maps*

6/26/2019

Sacramento State - Summer 2019 - CSc 130 - Cook

14

Dictionary Terminology

- The objects that are used for indices are called *keys*
- The objects that are accessed using the key are called *values*

6/26/2019

Sacramento State - Summer 2019 - CSc 130 - Cook

15

Databases vs. Dictionaries

- Dictionaries...
 - have a single key
 - that key is the only way to access data
 - key returns a single value
- Databases...
 - may have multiple keys
 - information can be accessed using other fields (e.g. SSN, name, age, etc...)
 - may return multiple objects – e.g. all the students taking CSc 130

6/26/2019

Sacramento State - Summer 2019 - CSc 130 - Cook

16

Implementing Dictionaries

- There are numerous approaches to implementing dictionaries
- Typically, it uses a *keyed-value* structure
 - a class stores a key object and data object
 - this can be stored in any data structure we have covered

6/26/2019

Sacramento State - Summer 2019 - CSc 130 - Cook

17

Implementing Dictionaries

- Using a linked list
 - adding takes $O(1)$
 - access is $O(n)$
- Unsorted array
 - add is $O(n)$ – have to resize
 - access is $O(n)$
- Sorted array
 - add is $O(n)$ – have to resize
 - access is $O(\log n)$

6/26/2019

Sacramento State - Summer 2019 - CSc 130 - Cook

18

This Ain't So Good

- So, adding in to an array is $O(n)$!
- Arrays seem like a poor approach
- Is there a better way to store dictionary data? Keeping adding close to $O(1)$?
- ... and keep access at $O(\log n)$
- Perhaps, we will learn that soon....

19

Binary Search Trees

Climbing a tree has never been so fun

Binary Search Trees

- *Binary Search Tree*, or *BST* for short, is a special type of binary tree that sorts nodes by value
- Basically,
 - all the nodes on the left branch are less than the current node
 - all the nodes on the right branch are greater than the current node

6/26/2019

Sacramento State - Summer 2019 - CS130 - Cook

21

Searching the Tree

- Since the tree divides the problem progressively by two, the time complexity is only $O(\log n)$
- Which gives that all the benefits of a sorted array
- Worst case is $O(n)$ – if the tree is a list-like chain

6/26/2019

Sacramento State - Summer 2019 - CS130 - Cook

22

Search logic (looking for S)

- If **S** is equal to the current node, you found it
- If **S** is smaller than the current node, take the left branch
- If **S** is bigger than the current node, take the right branch
- If there are no branches, **S** was not found

6/26/2019

Sacramento State - Summer 2019 - CS130 - Cook

27

Binary Search Trees vs. Arrays

- When data is inserted in a Binary Search Tree
 - traverses down the tree until it finds the correct location
 - it then add itself there and restructures the tree
 - hence, the tree remains sorted as new data is added
 - it requires only $O(\log n)$
- When data is inserted in an Array
 - it must be expanded when new elements are added
 - ...and compacted when elements are removed
 - these requires $O(n)$

6/26/2019

Sacramento State - Summer 2019 - CSc 130 - Cook

28

Inserting into the Tree

- Inserting is handled exactly like a search
- The only difference is that if the item is not found, the node is added
- If the item is not found,
 - we are already at the max-depth of the tree
 - we are at the node that needs to be changed
 - so, add a left or right node (based on value)
 - ... wow, this is easy!

Sacramento State - Summer 2019 - CSc 130 - Cook

33

Deleting From a Tree

- Deleting from a BST is a tad more tricky
- When the node is deleted, the tree needs to be re-linked to *still preserve the ordering*
- Fortunately, while the logic might seem a tad hard, it is fairly straight forward

6/26/2019

Sacramento State - Summer 2019 - CSc 130 - Cook

34

Deleting From a Tree

- Basically, we find a node to "*promote*" to the deleted node's position
- We need to find a value that is mathematically next to the deleted value

6/26/2019

Sacramento State - Summer 2019 - CSc 130 - Cook

35

There are 2 Options

- There are two equally valid options
- Choose one:
 - go down the left side and find the maximum node
 - ... or go down the right side and find the minimum node

Sacramento State - Summer 2019 - CS130 - Cook

45

This Might Get Crazy

- Internal nodes don't really change – but have a profound affect on the rest of the tree
- There are cases where the tree is unbalanced – one particular path contains all the data
- In this case, **the time complexity slowly deteriorates to $O(n)$**

6/26/2019

Sacramento State - Summer 2019 - CS130 - Cook

46

Sort in a Binary Search Tree?

- Unfortunately, while this might seem like a good idea, this is not a great solution
- Binary Search Trees can deteriorate into linked lists
- So...
 - $O(\log n)$ search can quickly deteriorate to $O(n)$
 - ...and $O(n \log n)$ sort can deteriorate to $O(n^2)$

6/26/2019
